Computer Vision Is More Than Image Classification

Computer Vision Is More Than Image Classification

ARTIFICIAL INTELLIGENCE · MACHINE LEARNING · DEEP LEARNING

SWIPE ->

A computer vision model can achieve 99% accuracy and still fail in production.

Here's why.

Image classification answers one question:

"What is in this image?"

But real-world computer vision systems often need to do much more:

- Object detection: Where are the objects?
- Segmentation: Which pixels belong to each object?
- OCR: What text is visible?
- Tracking: Where did the object move?
- Visual understanding: What is happening in the scene?

The difficult part isn't always recognizing an image.

It's handling different lighting conditions, unusual angles, blurry inputs, unseen objects, and images that don't look like the training data.

That's why I think choosing the right computer vision task is just as important as choosing the model.

Before asking, "Which model should I use?"

Ask, "What exactly do I need the system to understand?"
